DOUGLAS L. PARKER  
Director of Forest Pest Management

## INTRODUCTION

Tree losses caused by the spruce beetle, Dendroctonus rufipennis (Kirby), continued to be a significant problem in the spruce-fir forest type on the Fort Apache Indian Reservation during 1984. This outbreak was initially detected during the spring of 1981. During subsequent years, Forest Pest Management and the Bureau of Indian Affairs have conducted biological evaluations and loss assessment surveys concerning this spruce beetle outbreak (Ragenovich 1982, Linnane 1983, and Linnane and Telfer 1984).

This report documents surveys conducted to (1) estimate the number of newly attacked trees, (2) evaluate and predict the infestation trend, and (3) provide management alternatives and recommendations. Survey data were collected by Forest Pest Management and Bureau of Indian Affairs personnel during September and October 1984.

## TECHNICAL INFORMATION

Insect. Spruce beetle, Dendroctonus rufipennis (Kirby)

Host. Engelmann spruce, Picea engelmannii Parry

Life History and Evidence of Infestation. Schmid and Frye (1977) and Massey and Wygant (1954) describe the spruce beetle life cycle and behavior in detail. Briefly, Dendroctonus rufipennis predominantly has a 2-year life cycle, although 1- and 3-year life cycles have been described. The 3-year life cycle may be common on cold sites, i.e., high elevation north-facing slopes. Adult D. rufipennis usually attack host trees during June and July. Egg gallery construction and oviposition continue through the summer. Immature larvae are present by October and overwinter. Larvae resume feeding in spring and develop to pupae before summer. Pupae transform to adults which overwinter a second time. These insects emerge in late spring and early summer to attack new host material.

Spruce beetles generally prefer to attack green windthrown or other recently downed spruce. As a result, endemic beetle populations are always present, breeding in scattered down material, in the spruce-fir forest type. Outbreaks generally begin after a major forest disturbance (i.e., a large windthrow) creates an abundance of suitable breeding material. Beetle populations rapidly increase in the down material and then readily attack standing spruce. Under favorable conditions, outbreaks may persist until suitable large diameter, host material is depleted. On occasion, unfavorable climatic conditions, principally extreme cold, cause outbreaks to collapse.

Spruce beetle outbreaks are difficult to detect. Tree crowns fade approximately 1 year after attack; however, discolored needles may remain on twigs for only a short duration, making recently attacked trees difficult to separate from snags. Newly attacked trees can often only be detected by close examination for boring dust. Pitch tubes may or may not be readily visible.

#### History of Spruce Beetle on the Fort Apache Indian Reservation.

Ragenovich (1982) summarized the history of spruce beetle on the Fort Apache Indian Reservation as follows: "Large areas of spruce mortality were first detected in the White Mountains of the Fort Apache Indian Reservation in 1904. This mortality was most likely the result of spruce beetle activity. The first recorded spruce beetle outbreak occurred from 1948 to 1952, when an estimated 22 percent of the spruce was killed in the Ord Creek drainage. The next recorded outbreak occurred from 1968 to 1971 when beetle populations built up in down material and spread to standing green trees, killing tens of thousands of trees in five drainages. The outbreak subsided abruptly in 1971 when record-low temperatures caused high larval mortality."

Location and Extent of the Current Outbreak. This outbreak was initially detected in 1981. Subsequently, attacked trees have been detected throughout the spruce-fir type on reservation lands including the Mount Baldy Wilderness Area (figure 1). There are approximately 38,600 acres of type on the reservation. In 1982, an aerial detection survey estimated 100,000 fading spruce in this zone. The detection survey in 1983 estimated over 200,000 fading spruce, with approximately 75,000 of these trees occurring within the wilderness area. Outside the wilderness, the spruce-fir type has been divided into five management compartments. In 1983, Burnt Mountain and Bull Cienega compartments had high concentrations of fading spruce, while Diamond Butte, Tiger Butte, and Mount Ord compartments had fewer fading spruce than in the previous year. Spruce beetle activity also increased on adjacent lands within the Apache-Sitgreaves National Forests, principally in the Mount Baldy Wilderness Area.

In 1984, aerial detection surveys estimated 13,000 fading spruce on reservation lands, a substantial decrease from previous years. Approximately 9,000 of these currently fading spruce occurred within the Mount Baldy Wilderness Area.

Host Stand Condition. Infested stands are predominately spruce (approximately 60 percent of basal area); other principal species are corkbark fir, Abies lasiocarpa var arizoncia (Merriam) Lemm., aspen, Populus tremuloides Mich., and Douglas-fir, Pseudotsuga menziesii (Mirb.) Franco. Average diameter of live spruce is now approximately 15 inches. Stand basal areas range from 170 to 200 square feet per acre. Standing infested and dead spruce are abundant in many areas, as well as down spruce from past spruce beetle outbreaks.

The 1983 biological evaluation (Linnane and Telfer 1984) estimated current attacked spruce (1983) at 1.2 to 1.4 trees per acre. Spruce basal area losses attributed to the current outbreak were estimated to average 26 square feet per acre. Spruce volume losses have been estimated in excess of 100 MMBF.

## METHODS

Survey Design. Two survey methods were used to estimate current tree losses and the spruce beetle population trend. These were a systematic variable plot cruise and a sequential insect sampling plan.

Commercial spruce-fir stands on reservation land have been divided into five management compartments. A systematic variable plot cruise was conducted within all compartments. Cruise lines were located in cardinal directions across contour at 20-chain intervals over the entire spruce-fir forest type in each compartment. Variable sample plots were located along these lines at 5- or 10-chain intervals, depending on required sampling intensity.

Sampling intensity was determined using coefficient of variation estimates from the previous year's survey (Linnane and Telfer 1984) and in the following formula.

$$SE\% = \frac{CV}{\sqrt{n}} \quad \text{or} \quad n = \frac{(CV)^2}{SE\% ^2}$$

Where SE% = Acceptable sampling error  
CV = Coefficient of variation  
n = Sample size

For this survey, a 20-percent standard error of the mean was considered satisfactory precision. Based on these parameters, sample size was determined for each management compartment as follows:

Diamond Butte - 51 sample plots  
Mount Ord - 132 sample plots  
Bull Cienega - 74 sample plots  
Sunrise - 49 sample plots  
Burnt Mountain - 43 sample plots

All plots trees were tallied by species and diameter. Spruce was classed in one of five categories based on beetle activity: (1) Green--uninfested spruce; (2) current attacks (1984)--parent adult, eggs, or small larvae present; (3) previous attacks (1983)--fading foliage and large larvae, pupae, or adults present; (4) old attacks--no spruce beetle present and foliage mostly dropped; and (5) partial attacks--beetle attacks limited to one side of the bole and foliage still green.

A sequential sampling plan for spruce beetles in standing trees (Knight 1960) was utilized to evaluate infestation trend in areas of concentrated beetle activity. Knight's (1960) procedure classifies a particular infestation into the following categories: (1) Increasing--emerging beetles will kill more trees than presently infested; (2) static--they will kill about the same number; and (3) decreasing--they will kill fewer trees.

Active infestations were located using a sketch map drawn during a current aerial detection survey. Concentrations of greater than 50 fading spruce served to locate the general sampling area. Within each sampling area, two 6- by 6-inch bark samples were removed from opposite sides of the lower bole of each infested sample tree. Sample trees were assumed to have been attacked in 1983. All living spruce beetles beneath the bark samples were tallied. Sampling continued in each sampling area until the infestation trend could be classified under Knight's (1960) sequential plan. A minimum of 20 samples are required to reach a decreasing or increasing decision. A minimum of 38 samples are required to classify an infestation as static.

Data Analysis. Data from the variable plot cruise were compiled and analyzed using the "Pest" program stored at the Fort Collins Computer Center. This program provided the average trees per acre and basal area per acre estimates by damage categories, with standard deviation and standard error estimates. Data from the sequential brood sampling survey were tallied in the field and compiled in tabular form for each sampling location.

## RESULTS

Sampling Intensity. The systematic variable plot cruise was completed on 20,082 acres of spruce-fir forest type outside the Mount Baldy Wilderness. A total of 501 sample points were measured in the 5 management compartments (table 1).

The sequential brood sampling plan was conducted at five locations (figure 1).

Tree Losses. Basal area and trees per acre estimates for spruce beetle-attacked trees along with nonhost tree estimates by management compartment are presented in table 2. During 1984, new spruce beetle attacks ranged from 0.1 trees per acre in the Sunrise compartment to 6.4 trees per acre in the Burnt Mountain compartment. Basal area estimates for currently attacked spruce ranged from 0.5 square feet per acre in the Sunrise compartment to 7.2 square feet per acre in the Burnt Mountain compartment.

The spruce component killed or infested by spruce beetles during this recent outbreak is substantial. The basal area loss estimates by management compartments were 26 percent-Diamond Butte, 18 percent-Mount Ord, 19 percent-Bull Cienega, 7 percent-Sunrise, and 40 percent-Burnt Mountain.

Stand Structure and Composition. Stand tables for spruce and other nonhost tree species by management compartment are presented in tables 3 through 22.

Total stand basal areas ranged from 157 to 239 square feet per acre, with spruce representing an average 72 percent of the overstory basal area. Other major tree species included corkbark fir (12 percent basal area), Douglas-fir (12 percent basal area), and aspen (4 percent basal area).

Infestation Trend. The sequential brood sampling plan and the variable plot cruise data were indicators of infestation trend.

Sequential brood sampling results are presented in table 24. All five sample locations easily fell within the increasing category. Emerging beetles should kill more trees than currently infested at least in the vicinity of sampling locations.

Although the brood sampling was accomplished in October, the majority of spruce beetles found under the bark were large larvae. Adults were present in lower than expected numbers; however, little evidence of hibernators (adult beetles which emerge and then reenter the lower tree bole) was found. Emergence holes in the bark samples were common, although not in significant numbers. Sample trees all had signs of fading foliage and obvious woodpecker activity.

The variable plot cruise data estimated the number of newly attacked trees per acre, indicating infestation trend. During 1984, beetle activity in Diamond Butte, Bull Cienega, and Burnt Mountain management compartments occurred at a higher frequency than estimates from the 1982 and 1983 attack periods (Linnane 1983, Linnane and Telfer 1984). Table 23 summarizes estimates for newly attacked spruce per acre and total numbers of newly attacked trees by management compartment.

## DISCUSSION

The spruce beetle has had a significant impact on timber stands within the Fort Apache Indian Reservation. A high percentage of the large diameter spruce (>25 inches d.b.h.) has been killed and up to 40 percent of the spruce basal area has been lost (Burnt Mountain compartment).

The 1984 survey results indicate tree losses can be expected to continue during 1985. The variable plot cruise estimated a significant number of new attacked trees occurred during 1984. The brood sampling estimates indicated a sufficient number of adult beetles should be available for the 1985 flight period to successfully attack more trees than currently infested. However, the ability of spruce beetles to locate and successfully attack new host trees will be tested, since a high percentage of the most suitable host trees has already been killed.

During the sequential brood sampling survey, we expected to observe primarily callow and new adult insects under the bark. This was not the case. The insects were principally large or mature larvae. Also, little evidence of hibernators was found. While the 2-year life cycle described by Massey and Wygant (1954) is considered generally applicable (Schmid and Frye 1977), variations in life cycle length are not uncommon (Knight 1961, McCambridge and Knight 1972). Knight (1961) reported "a normal life cycle is difficult to describe; the variations due to environmental conditions are such that no two cycles are alike." On the Fort Apache Indian Reservation, variations from

the 2-year life cycle appear common. These variations may be either 1- or 3-year versions of the spruce beetle life cycle. The life cycle issue is further confused by the existence of high number of partially attacked trees (Linnane 1983, and Linnane and Telfer 1984), making it difficult to establish the year of attack.

### MANAGEMENT ALTERNATIVES

Alternative actions considered for the current spruce outbreak have been described in detail by Linnane and Telfer (1984). They are summarized as follows:

1. No action, including:<sup>1</sup>
  - a. Salvage logging
  - b. Presalvage logging
2. Direct suppression, including:
  - a. Treatment of individual infested trees
  - b. Trap trees
3. Preventive insecticidal spray

### RECOMMENDATIONS

During recent years, a combination of salvage and presalvage logging has been implemented in the outbreak area. We recommend this action be continued.

In designing salvage or presalvage operations, residual stand wind-firmness is an important consideration. Also, any logging operations should be closely monitored to insure a minimum of logging debris remains. Stump height should be kept below 1.5 feet. Cull logs and tops should be bucked into short lengths and scattered in open areas. Log decks containing infested material should be removed to millsites prior to beetle flight.

---

<sup>1</sup>Salvage and presalvage logging have little or no effect on the outbreak progress.

TABLE 23.--Estimates of new spruce beetle attacks (1984) on the Fort Apache Indian Reservation

Management compartment	Current attacks trees per acre (S.E.)	Total number current attacks (Trees <sup>1</sup> )
Diamond Butte	5.2 (1.5)	12,882 to 23,551
Mount Ord	1.4 (0.8)	3,452 to 14,184
Bull Cienega	3.6 (1.7)	7,783 to 21,171
Sunrise	0.1 (0.1)	1 < to 787
Burnt Mountain	6.4 (1.8)	15,377 to 27,549

<sup>1</sup>Lower and upper estimates based on one standard error (68% confidence limits)

TABLE 24.--Results of sequential brood sampling survey, 1984, Fort Apache Indian Reservation

Sample location	Number samples <sup>1</sup>	Total number insects	Infestation trend prediction
Wolhenberg Draw (section 5)	26	181	Increasing
Paradise Creek (section 8)	20	377	Increasing
Paradise Butte (section 16)	22	166	Increasing
Smith Cienega (section 10)	20	226	Increasing
Bull Cienega (section 15)	20	210	Increasing

<sup>1</sup>The number of bark samples taken to reach an infestation trend decision.
